

Supplementary Materials for Log-F-penalized Conditional Logistic Regression for Sparse Data

Ying Yu, Jiying Wen, Jinko Graham, Brad McNeney

In these supplementary materials we give further details on the analyses of the DES and trio data and provide a table of the complete simulation results.

1 DES data analysis

1.1 Load packages and functions

We use the following packages:

- `survival` for its `clogit()` function that performs unpenalized conditional logistic regression (UCLR)
- `coxphf` for its `coxphf()` function (Firth-penalized Cox proportional hazards) that is called by `clogitf()` (see below) do to Firth-penalized conditional logistic regression (FCLR), and
- `tidyverse`

We also load R source files that contain code for the analyses. These files are loaded from local copies, but are also available on GitHub at https://github.com/SFUStatgen/logF_CLR.

- `clogitf.R`: contains the functions `clogitf()` for Firth-penalized conditional logistic regression, following a suggestion by G. Heinze, and `clogitlogF()` for log-F-penalized conditional logistic regression (logFU and logFW).
- `logFmatched.R`: contains the function `augment.logFmatched()` that augments an input data frame by the pseudo-matched sets needed for log-F-penalized conditional logistic regression.

```
library(survival)
library(coxphf)
library(tidyverse)

## Warning: package 'ggplot2' was built under R version 4.4.3

```

1.2 DES data

The DES data are available from the GitHub repository.

```
des <- read.csv("DES.csv")
```

```
des$matchedset <- des$matched.set # Our code requires that var name is matchedset
des <- select(des,matchedset,case,DES,matern.smoke)
summary(des)
```

```
##      matchedset      case      DES      matern.smoke
## Min.   :1.00   Min.   :0.0   Min.   :0.000   Min.   :0.0
## 1st Qu.:2.75   1st Qu.:0.0   1st Qu.:0.000   1st Qu.:0.0
## Median :4.50   Median :0.0   Median :0.000   Median :1.0
## Mean   :4.50   Mean   :0.2   Mean   :0.175   Mean   :0.7
## 3rd Qu.:6.25   3rd Qu.:0.0   3rd Qu.:0.000   3rd Qu.:1.0
## Max.   :8.00   Max.   :1.0   Max.   :1.000   Max.   :1.0
```

```
xtabs(~DES + case + matern.smoke,data=des)
```

```
## , , matern.smoke = 0
```

```
##
```

```
##      case
```

```
## DES  0  1
```

```
##      0 11  0
```

```
##      1  0  1
```

```

```

```
## DES  0  1
```

```
##      0 21  1
```

```
##      1  0  6
```

UCLR fails:

```
form <- formula(case ~ DES + matern.smoke)
```

```
des.aug0 <- augment.logFmatched(form,des,m=0)
```

```
UCLR <- try(clogitlogF(form,des.aug0,maxit=500))
```

```
## Warning in coxph.fit(X, Y, istrat, offset, init, control, weights = weights, :
```

```
## Loglik converged before variable 1,2 ; coefficient may be infinite.
```

```
## Warning in coxph.fit(X, Y, istrat, offset, init, control, weights = weights, :
```

```
## Loglik converged before variable 1 ; coefficient may be infinite.
```

```
## Warning in coxph.fit(X, Y, istrat, offset, init, control, weights = weights, :
```

```
## Loglik converged before variable 1 ; coefficient may be infinite.
```

FCLR works but throws a warning unless you run it for many iterations.

```
FCLR <- clogitf(form,des,maxit=500)
```

```
FCLR
```

```
## coxphf(formula = newformula, data = data, pl = pl, alpha = alpha,

```

```
##      lower      upper
## 4.372844 465.987077
```

We also plot the profile penalized log likelihoods. For the log-F approaches we do this by fixing the DES effect and maximizing over the maternal smoking effect, with the DES effect included as an offset. For FCLR we use the output of the `coxphfplot()` function.

```
profile_ll_logF <- function(beta_t,augdata) {
  offset <- beta_t * augdata$DES
  form <- formula(case ~ matern.smoke + strata(matchedset) + offset(offset))
  fit_t <- survival::clogit(form, data = augdata, weights = augdata$weights,
                           method = "efron")
  fit_t$loglik[2]
}
profile_ll_FCLR <- function(formula,data) { # Suggestion from Heinze
  require(coxphf)
  data$start = data$matchedset
  data$stop = data$matchedset+0.1
  # Change response as done in clogit()
  newformula = formula
  newformula[[2]]=substitute(Surv(start,stop,case),list(case=formula[[2]]))
  environment(newformula) = environment(formula)
  p <- coxphfplot(formula=newformula,data=data,profile=~DES)
  return(p)
}
```

Now run these functions to obtain the profile penalized log likelihoods for all the methods.

```
fcldr <- profile_ll_FCLR(form,des)
```

```
beta_t <- fcldr[,"DES"]
fcldr <- fcldr[,"log-likelihood"]
```

```

uclr <- logfu <- logfw <- rep(NA,length(beta_t))
for(i in seq_along(beta_t)) {
  uclr[i] <- profile_ll_logF(beta_t[i],des.aug0)
  logfu[i] <- profile_ll_logF(beta_t[i],des.augU)
  logfw[i] <- profile_ll_logF(beta_t[i],des.augW)
}
mm <- factor(rep(c("UCLR","FCLR","logFU","logFW"),each=length(beta_t)),
             levels=c("UCLR","FCLR","logFU","logFW"))
plotdat <- data.frame(logGRR=rep(beta_t,4),profl=c(uclr,fclr,logfu,logfw),
                     method=mm)

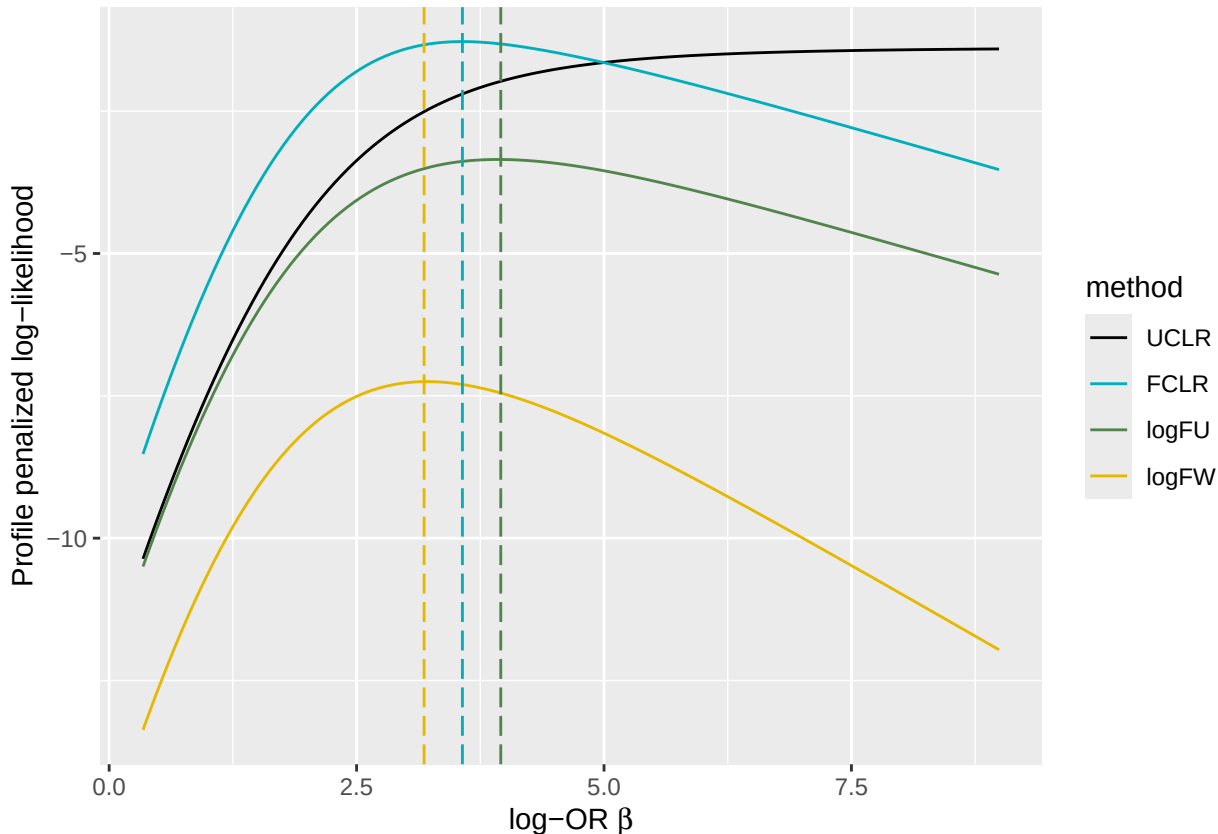

```

Finally, we can plot the curves.

```

ggplot(plotdat,aes(x=logGRR,y=profl,color=method)) + geom_line() +
  scale_color_manual(values=c("black","#00AFBB","#52854C","#E7B800")) +
  xlab(expression(paste("log-OR ",beta))) +
  ylab("Profile penalized log-likelihood") +
  geom_vline(xintercept=beta_t[which.max(fclr)],
             linetype="longdash", color="#00AFBB") +
  geom_vline(xintercept=beta_t[which.max(logfu)],
             linetype="longdash", color="#52854C") +
  geom_vline(xintercept=beta_t[which.max(logfw)],
             linetype="longdash", color="#E7B800")

```

2 Trio data analysis

2.1 Purpose

This document reconstructs the case-parent trio analysis used in the manuscript. It explains the conditional-likelihood formulation, shows how Mendelian transmission probabilities enter as offsets in conditional logistic regression, and fits an additive per-allele model for the Z+2 allele at the *GCK1* microsatellite locus.

The reconstructed data are based on the counts reported by Frayling et al. (1999). The affected child is treated as the case, and the genotypes that could have been transmitted by the same parents are treated as matched pseudo-controls. Parental mating type defines the matched set.

2.2 Data and notation

Let

- $G \in \{0, 1, 2\}$ denote the number of copies of the Z+2 allele carried by the child;
- $G_p = (g_{p1}, g_{p2})$ denote the parental Z+2 allele counts;
- $D = 1$ identify the observed affected child and $D = 0$ identify a pseudo-control genotype.

The original draft described the genetic variants as SNPs. That is not correct for this application: *GCK1* is a microsatellite locus, and Z+2 is one of its alleles.

The reported affected-child counts are:

```
affected_counts <- data.frame(
  mating = c("0x1", "0x1", "1x1", "1x1"),
  observed_g = c(0, 1, 0, 1),
  n = c(10, 15, 1, 1)
)
```

affected_counts

```
##   mating observed_g  n
## 1    0x1          0 10
## 2    0x1          1 15
## 3    1x1          0  1
## 4    1x1          1  1
```

2.3 Conditional likelihood for trio data

Conditional on parental mating type G_p , the probability that the affected child has genotype g is proportional to

$$\exp\{z(g)^T \beta\} P(G = g \mid G_p),$$

where $P(G = g \mid G_p)$ is the Mendelian transmission probability. Thus the likelihood contribution of one trio is

$$\frac{\exp\{z(g)^T \beta\} P(G = g \mid G_p)}{\sum_{g^*} \exp\{z(g^*)^T \beta\} P(G = g^* \mid G_p)}.$$

This has the form of a conditional logistic likelihood with linear predictor

$$z(g)^T \beta + \log P(G = g \mid G_p).$$

Therefore, the logarithm of the Mendelian transmission probability enters the conditional logistic regression as an offset.

Because an additive constant within a matched set cancels from the conditional likelihood, one may use either the exact log probabilities or any proportional weights. For a 1×1 mating, for example,

$$P(G = 0 \mid G_p) = \frac{1}{4}, \quad P(G = 1 \mid G_p) = \frac{1}{2}, \quad P(G = 2 \mid G_p) = \frac{1}{4}.$$

The exact offsets are $\{\log(1/4), \log(1/2), \log(1/4)\}$. Subtracting the common value $\log(1/4)$ gives the equivalent offsets

$$\{0, \log 2, 0\}.$$

2.3.1 Additive per-allele model

The manuscript reports a single genotype relative risk for each additional copy of the Z+2 allele. The corresponding model is

$$z(g) = g$$

and

$$\text{GRR} = \exp(\beta).$$

This is different from a two-parameter model with separate genotype effects. If one writes

$$z(g) = \begin{cases} (0, 0), & g = 0, \\ (1, 0), & g = 1, \\ (1, 1), & g = 2, \end{cases}$$

then the parameters are log relative-risk increments:

$$\exp(\beta_1) = \frac{P(D = 1 \mid G = 1)}{P(D = 1 \mid G = 0)}, \quad \exp(\beta_2) = \frac{P(D = 1 \mid G = 2)}{P(D = 1 \mid G = 1)}.$$

The β_j themselves are log-GRRs, not GRRs. In these reconstructed data, no affected child has genotype $G = 2$, so the two-parameter model has no information about β_2 . The single-parameter additive model is therefore the model used below.

2.4 Reconstructing the matched pseudo-control data

For a 0×1 mating, the possible offspring genotypes are 0 and 1, each with probability $1/2$.

For a 1×1 mating, the possible offspring genotypes are 0, 1, and 2, with probabilities $1/4$, $1/2$, and $1/4$, respectively.

Each observed affected child defines one matched set. The observed genotype is coded as the case, and the other possible offspring genotypes are coded as pseudo-controls.

```
make_set <- function(stratum, mating, observed_g) {
  if (mating == "0x1") {
    # Mendelian probabilities: P(G=0)=1/2, P(G=1)=1/2
    g <- c(0, 1)

  } else if (mating == "1x1") {
    # Mendelian probabilities: P(G=0)=1/4, P(G=1)=1/2, P(G=2)=1/4
    # Represent these probabilities by multiplicities 1:2:1.
    g <- c(0, 1, 1, 2)

  } else {
    stop("Unsupported mating type: ", mating)
  }

  case <- integer(length(g))
}
```

```

# Mark exactly one copy of the observed genotype as the affected child.
observed_rows <- which(g == observed_g)

if (length(observed_rows) == 0L) {
  stop(
    "Observed genotype ", observed_g,
    " is incompatible with mating type ", mating, "."
  )
}

case[observed_rows[1L]] <- 1L

data.frame(
  stratum = stratum,
  mating = mating,
  g = g,
  case = case
)
}

sets <- vector("list", sum(affected_counts$n))
s <- 1L

for (i in seq_len(nrow(affected_counts))) {
  for (j in seq_len(affected_counts$n[i])) {
    sets[[s]] <- make_set(
      stratum = s,
      mating = affected_counts$mating[i],
      observed_g = affected_counts$observed_g[i]
    )
    s <- s + 1L
  }
}

trio_dat <- do.call(rbind, sets)
row.names(trio_dat) <- NULL

head(trio_dat, 12)

```

```

##      stratum mating g case
## 1         1     0x1 0    1
## 2         1     0x1 1    0
